PGS is a population-based 3D genome-modeling package implemented in Python. The software takes Hi-C matrix and chromosome regions segmentation or topological associated domains(TADs) information, which then generates an ensemble of structure population. The software also automatically generates analysis reports, such as structure quality based on scoring parameters, plots of radial positions and contact frequency maps from the structures. The whole codes are wrapped in Python, and users can simply execute it one time.

**Note:** PGS software will run on high performance computing environment (HPC), such as sun grid engine and TORQUE (pbs script), as well as local machine. But, it is highly recommended to run on HPC because of computational resource and running time.

The code is open source, and [available on github](#).

Here is the overview of PGS pipeline:

Contents:

### Installation

Requirements:

- Python 2.7
- Python packages `numpy`, `scipy`, `pandas`, `h5py`, `matplotlib`, `seaborn`
- IMP (Integrative Modeling Package.)

Conda package is recommended to install all the requirements. Either [Anaconda](#) or the minimal [Miniconda](#) are suitable for managing required packages including IMP. If you use Miniconda, then you can install as follows:

```
$ conda install numpy scipy pandas h5py matplotlib seaborn
```

Install IMP using conda:

```
$ conda config --add channels salilab  
$ conda install imp
```

All other dependencies for `imp` and python packages will be automatically installed.

Then install PGS workflow packages:

```
$ python setup.py install
```

To test if the installation goes well, the following command can be executed:

```
$ cd test  
$ ./runPgs_workflow_test.sh
```

## PGS Helper GUI

PGS package includes a Graphical User Interface (GUI) based helper program for user to run PGS easily. With this, a user can generate a command script `runPgs.sh` and a configuration file `input_config.json`.

---

**Tip:** PGS Helper uses [Java Runtime Environment](#), the latest Java SE 8 update is recommended.

---

---

**Note:** PGS Helper is a convenient interface but not required to run PGS. We also provide the `runPgs.sh` and `input_config.json` examples that are easy to modify (*PGS Helper Output*) without using the GUI.

---

## Using the PGS Helper

To initialize PGS Helper:

```
$ java -jar PGSHelper.jar
```

The following GUI will appear:

**PGS Helper V0.0.1**

**Working Directory**  
 **Browse**

**PGS Source**  
**Directory**  **Browse**

**Input**  
☒ **Raw + TAD**    ☐ **TAD-TAD Prob(txt) + TAD**    ☐ **TAD-TAD Prob(hdf5)**  
**Raw matrix(txt)**  **Browse**  
**TAD file(.bed)**  **Browse**  
**Genome**  **Resolution**

**Modeling Parameters**  
**Num of structures**  **Violation cutoff**   
**Theta list**   
**Max iteration**  **Chr Occupancy**   
**Nucleus Radius**

**System Parameters**  
**Default core(per job)**  **Default mem MB(per job)**   
**Max core(per job)**  **Max mem MB(per job)**

**Command Setup(pyflow Arguments)**  
**Run mode** ☐ **local**    ☐ **SGE**    ☒ **Torque**  
**Core limit**  **Mem limit(MB)**   
**Optional argument list**

**Usage**  

```
> cd /home/$PROJECT_DIR
> sh runPGS.sh
```

**Reset** **Generate**

## A. Working Directory

Specify the project/working directory using the **Browse** button on right side. PGS will run in the specified project directory and all files, such as running script(i.e. `runPGS.sh`), configuration file(i.e. `input_config.json`), log(i.e. `pyflow.data`), and output results, will be stored in the directory.

## B. PGS Source – Directory

Specify the directory of PGS source code using the **Browse** button on right side.

## C. Input

Contact frequency matrix file format						Chromosome segmentation (TADs)			
chr1	0	2500000	25232	21011	...	chr1	0	2500000	domain
chr1	2500000	6000000	21011	30028	...	chr1	2500000	6000000	domain
chr1	6000000	8000000	17804	19990	...	chr1	6000000	8000000	domain
chr1	8000000	11000000	10553	12537	...	chr1	8000000	11000000	domain
...	...	...	...	...	...	...	...	...	...
chr1	121500000	143500000	1910	2005	...	chr1	121500000	143500000	CEN
chr1	143500000	144500000	1801	2244	...	chr1	143500000	144500000	gap
chr1	144500000	146000000	1302	1299	...	chr1	144500000	146000000	domain
chr1	146000000	149500000	993	877	...	chr1	146000000	149500000	gap
...	...	...	...	...	...	...	...	...	...
chrX	150000000	152000000	12	6	...	chrX	150000000	152000000	domain
chrX	152000000	155270560	0	0	...	chrX	152000000	155270560	domain

3-column bin info
matrix
3-column TAD info
flag

**Note:** Currently our pipeline only support diploid genome, so chromosome Y is not supported and please don't include it in the input file. We will be updating the support for chromosome Y soon.

- Experiment data

### Option 1 : Raw + TAD

- Raw contact matrix file (txt); the first three columns contain chromosome, start position (bp), and end position (bp) and followed by contact matrix (all numeric values must be **integers**; see figure above).
- TAD\_file (bed); a 4-column chromatin segmentation or TAD file, we adopt **bed file format** while the 4-th column must contain “domain”, “CEN”, and “gap” (see figure above).

### Option 2 : TAD-TAD Prob(txt) + TAD

- Probability matrix file (txt); adopts the same format as the raw contact matrix file above, but the matrix contains probability values from 0 to 1.
- TAD\_file (bed); the format as figure above.

### Option 3 : TAD-TAD Prob(hdf5)

- Probability matrix file (hdf5) : if a user have generated probability matrix using PGS (i.e. under old \$PROJECT\_DIR/result/probMat/probMat.hdf5.hmat), then the user can use the previous probability matrix. This process will skip the first workflow, buildTADMap task. This option is good for replica calculations (in a new working directory, of course).
- Genome : the genome version of 3D models being constructed (current PGS supports chromosomes 1-22 and X).
- Resolution : the resolution of raw input data (in bp).

## D. Modeling Parameters

- Num of structures : the number of structures to generate. default = 1,000
- Violation cutoff : violation cutoff. default = 0.05

- Theta list : a probability list for step-wise optimizations;  $1 > \text{theta} > 0$ . default = 1, 0.2, 0.1, 0.05, 0.02, 0.01
- Max iteration : the number of maximum iterations for each theta. default = 10
- Chromosome Occupancy : the expected ratio of chromosome volume in the nucleus. default = 0.2
- Nucleus Radius : assumed radius (nm) of cell nucleus. Changing this value will change the relative size of each domain sphere. default = 5000.0

## E. System Parameters

In order to proceed efficiently, PGS submits both single-core and multi-thread jobs on HPC clusters (e.g. for the M-step and A-step jobs, respectively). Thus the following parameters need to be specified. - Default core : the number of cores to use for each regular job. - Default MemMB : the memory (Mb) to use for each regular job. - Max cores : the number of cores to use for each multi-thread job. - Max MemMB : the total memory (Mb) to use for each multi-thread job.

## F. Command Setup

- Run mode : select a platform such as local computer, Sun Grid Engine (SGE) or Torque.
- Core limit : the maximum number of cores for PGS to use (limited to user's quota).
- Mem limit : the limit of memory for PGS to use.
- Optional argument list : additional options for each job to run/be assigned properly on the user's HPC, such as queue name, running time, etc. Example arguments for PBS jobs: [ '-l', 'your\_qname\_here', '-l', 'walltime=333:00:00' ]. Note that the option list will be applied to each job.

## G. Generate Scripts

Click the `Generate` button on the bottom to write a file (`input_config.json`) with the parameters on the working directory which has been specified by the user. There will be a confirmation window with `Yes` or `No` button, and at this point the user can see a simple instruction in the `Usage` box. If `Yes` is clicked, then the GUI will be closed.

## PGS Helper Output

PGSHelper writes configuration in `input_config.json`, and a shell script (`runPGS.sh`) under the project directory. The following describes the contents of those 2 files.

1. `$PROJECT_DIR/input_config.json`

```
{  "source_dir" : "[Directory name where pgs source is]",
  "input" : {
    "raw_matrix_file" : "[raw matrix file]",
    "TAD_file" : "[ TAD file, .bed format]",
    "resolution" : "[Resolution of input contact_map_file, e.g. 100000]",
    "genome" : "[Genome version, e.g. hg19]"
  },
  "output_dir" : "[Output Directory to store the results, e.g. $PROJECT_DIR/result]
↪",
  "modeling_parameters" : {
```

```
"theta_list" : [Theta list e.g, "1", "0.2", "0.1", "0.05", "0.02", "0.01"],
"num_of_structures" : [Number of structure to generate, e.g. 1000],
"max_iter_per_theta" : [Max Iterations per job, e.g. 10],
"violation_cutoff" : [Violation Cutoff, e.g. 0.05]
"chr_occupancy" : [Chromosome Occupancy, e.g. 0.2]
"nucleus_radius" : [Nucleus Radius (nm), e.g. 5000.0]
},
"system" : {
  "max_core" : [Maximum number of cores in a single node],
  "max_memMB" : [Maximum size of mem(MB) in a single node],
  "default_core" : [Default number of cores],
  "default_memMB" : [Default size of mem(MB)]
}
}
```

2. \$PROJECT\_DIR/runPGS.sh

```
python $PGS_DIRECTORY/pgs.py
--input_config $PROJECT_DIR/input_config.json
--run_mode [running platform]
--nCores 300
--memMb 800000
--pyflow_dir $PROJECT_DIR
--schedulerArgList ["-q", "qname", "-l", "walltime=100:00:00"]
```

## RUN PGS

User can execute PGS under the project/working directory with the following command.

```
$ sh runPgs.sh
```

---

### Expected Results

---

A successful PGS execution will generate a `result/` folder which composed of 4 subfolders:

- `probMat/` : contains the input hdf5 TAD-TAD probability matrix (if option 1 or 2 is used).
- `actDist/` : contains intermediate files generated by A-step (restraint assignment step). A file is generated at each A/M iteration, and will be used in the subsequent M-step (model optimization).
- `structure/` : contains structure information files. One `.hms` file has snapshot coordinates of a model with different optimization steps depending on theta parameters.
- `report/` : contains preliminary analysis with some plots.

The following we describe results under `report/` folder.

#### heatmap

Contains genome-wide heat map plots of contact probabilities, calculated from both the model population and experiment data (input matrix). A figure showing density scatter plots (log-log scale) as a comparison between them is also provided.

#### intraMatrix

Contains heat map plots of contact probabilities for every chromosome, calculated from both the model population and experiment data (input matrix).

#### radialPlot

Contains scatter plots of mean radial position of all TADs, organized by chromosomes in pdf files. The mean radial positions are also recorded in a text file `radialPlot_summary.txt`.

## **violations**

Contains a text file that tells the average portion of violated restraints per model.

**Analysis tools to get results shown under the `report/` directory**

PGS package provides tools for analyzing the final structure population (see [Alberlab API Reference](#)). The following are some examples of how to extract information from the structure-population.

First, identify which model you would like to see, e.g. `result/structure/copy0.hms`. You can check group names in the file using a simple bash command:

```
$ h5ls result/structure/copy0.hms
```

And something like this will appear:

```
0.01b          Group
0.01a          Group
0.01           Group
0.05           Group
0.1            Group
0.2            Group
1              Group
genome         Dataset {SCALAR}
idx            Dataset {2320}
```

In that example, the “idx” has information of 2320 TADs and it saves iteration snapshots at  $\theta = \{1, \dots, 0.01, 0.01a, 0.01b\}$ . Thus the final structure is in group “0.01b” (at theta level  $p=0.01$  there are 3 A/M iteration cycles).

- **Getting the 3D coordinates of the genome**

```
import alab
hmsfile = 'result/structure/copy0.hms'
problvl = '0.01a'
hms = alab.modelstructures(hmsfile, [problvl])
TADidx = hms.idx #TADs information
xyz = hms[0].xyz #diploid set of coordinates
```

Now the user can use the coordinates, stored in `xyz`, to do any analysis. The TAD information with genomic location is stored in `TADidx` variable. In the following we provide some other usage of coordinates.

- **Getting the contact probability map** We show example lines on how to get contact probability maps under `result/report/heatmap` and `result/report/intraMatrix`

```
import alab

hmsfiledir = 'result/structure'
problvl = '0.01a'
nstruct = 1000
summary = alab.structuresummary(hmsfiledir, problvl, nstruct)
m = summary.getContactMap()
m.plot('heatmap.png', format='png', clip_max=1)
m.makeIntraMatrix('chr1').plot('chr1_heatmap.pdf', format='pdf', clip_
↪max=1)
```

- **Getting the radial position** Radial position of a TAD is calculated by the average radial positions across the structure population of that TAD. 0 marks the center of nucleus, and 1 marks nuclear envelope.

```
rp = summary.getBeadRadialPosition(beads=range(len(summary.idx)*2))
rp_mean = rp.mean(axis=1)
rp_hapmean = (rp_mean[:len(summary.idx)]+rp_mean[len(summary.idx):])/2
```

- **Getting PDB** Some users might wish to get the coordinates and radii in a PDB format, maybe for visualization purpose. Hence we provide some nice scripts under `tools/` directory. Simply execute the following shell command under `$PROJECT_DIR/`:

```
$ tools/hms_export.py result/structure/copy0.hms 0.01b copy0.pdb
```

The script takes 3 arguments (hmsfile, theta\_group, and output\_name), then a pdb file will be saved and it will look something like this:

ATOM	1	PAM	A1	a	1	2899.1	58.6	855.0	218
ATOM	2	PAM	A1	a	2	3029.7	286.1	1257.0	244
ATOM	3	PAM	A1	a	3	2575.2	106.8	1117.7	202
....	.	...	...	.	.	.....	.....	.....	...
....	.	...	...	.	.	.....	.....	.....	...
ATOM	1214	QAM	BX	w	65	-2206.8	183.8	2465.6	202
ATOM	1215	QAM	BX	w	66	-2452.5	434.7	3049.5	238

#### Note:

- The 2nd column marks the TADs ids.
- PAM and QAM marks the short and long arms of a chromosome, respectively.
- CEN marks the centromere representative TAD.
- Chromosome homologue (4th column) is labeled as the chromosome name preceeded with A or B, e.g. A1 = the first homolog of chr1, BX = the 2nd homolog of chrX.
- The first half of coordinates belong to the first diploid copy, the second half contains the homologues.
- Chain name (5th column) is unique for each chromosome (e.g. chains “a” to “w” are for chr1 to chrX, respectively).
- The 6th column contains TADs order in a chromosome.

- Columns 6-8 record the 3D coordinates.
  - Column 9 stores the TADs radii.
  - In human genome 3D models, the nuclear radius is set to 5000 nm.
- 

- **Getting the structure-population summary file** Instead of analyzing structures from many files, user can also aggregate the final structure population into a file and ignore the intermediate snapshots. Let the final population be in “001b” group, thus the following shell command should be run:

```
$ tools/hms_to_hss.py result/structure/ 1000 0.01b structures_001b.hss
```

This command outputs a summary file called “structures\_001b.hss” which contains all coordinates of the last optimized structure population, their radii, TAD information, optimization scores, etc. At this point, if the user is not interested in the structures at intermediate steps, all `structure/copy*.hms` files can be deleted to release some disk space.

**Warning:** Check the content of the summary file (hss) first before deleting the \*.hms files!

## Frequently Asked Questions

### FAQ

We are happy to update this list with your questions, please write them on the [GitHub page](#).

1. **What is PGS for?** It is a user-friendly software package to compute 3D genome structures from contact frequency data (e.g. Hi-C matrix). Since it generates a lot of structures (population), it is better to run it on HPC clusters. Be ready to give a generous amount of disk space (a typical intermediate structure file can be ~4MB. But once a structure summary file is created (~1.2 GB for 10,000 structures), the intermediate files can be deleted).
2. **Should I edit the text under “Optional argument list” of PGS helper?** Yes, you should. Replace "qname" with your queue on HPC, but please do not delete the quote marks there (you may also delete this option and its value if you usually do not need to specify it when you submit jobs). Replace hh:mm:ss with number of hours, minutes, and seconds you wish to limit the time for a job to run. You can also add additional options with similar syntax (place a pair of quotes for each new option and its value, separated by a comma, and keep the brackets as it is).
3. **How long should I expect the PGS to complete 1,000 structures?** It depends on the computing power you assign it to. A typical M-step for 2 x 2320 TADs can take around 45 minutes on our HPC cluster (2.6 GHz speed). It will also depend on the theta list you set (correspond to A/M iteration cycles). The lower theta value will give more restraints to optimize, thus the longer is an A/M cycle. If you have 1,000 cpus running for PGS, and there will be 10 A/M cycles, you might get the final population in ~8 hours.
4. **Some nodes of my computing clusters crashed and some of PGS jobs were terminated, what should I do?** No worries, PGS can resubmit the fail jobs for you automatically and continues without problems. If PGS is still running, you do not need to do anything, just wait.

**Warning:** Do not alter `pyflow.data/` during PGS run. It contains logs and workflow state information. Deleting this folder will cause PGS to run from the beginning of the workflow again.

5. **I accidentally killed the terminal where PGS is running, how should I proceed PGS?** No worries, just go

to the working directory and execute the PGS again using the exact same command (`sh runPgs.sh`). PGS is capable of tracking the last interruption and restarting the workflows from there without hassle (as long as the last workflow state recorded in `pyflow.data/` remains valid).

6. **PGS was terminated because of errors before creating any results, what should I do?** You can first check the log files created under `pyflow.data/logs/` and try to fix that problems. However, in most cases the failures come from the input files, e.g. the matrix file or TAD file. Here are some points to check while fixing the error(s):
  - Make sure all formatting rules are met.
  - The Hi-C matrix should represent a complete genome (include gaps so it is continues) in uniformly-sized bins.
  - TADs representation must be continues (include gaps and centromeres and label them as “gap” and “CEN”, respectively. Every chromosome has one “CEN”). Of course, the size of TADs can differ.
  - All numeric must be integers (Hi-C counts, TAD genomic loci, etc.) except probability values (floating number from 0 to 1).
7. **What is TAD and how to get it for PGS run?** TAD (Topologically Associating Domain) is a continuous genomic region within which interact relatively frequently, whereas interactions across a TAD boundary occur relatively infrequently. Depending on the genome, their size can vary from tens of kb to a few Mb. We think this is a good chromosomal unit for 3D models. There are many TAD calling algorithm out there you can use. Ours is pretty much simple and quick, it’s called [TopDom](#) and can be [downloaded here](#).
8. **How many structures do I need to generate?** We think it will depend on your analysis, but in general the more the better. The radial position of chromosomes or TADs, for example, are relatively stable so that hundreds to a thousand of structures are good enough. To reproduce the Hi-C map that comes from million of cells, we need around 10,000 structures. Beyond that we may gain marginal increase of correlations but computational costly. If the object of study, e.g. higher order interactions, are rare events like ~1%, consider getting at least 10,000 structures.
9. **What is `probMat.hdf5.hmat` under `result/probMat/` folder?** It is a TAD-TAD probability matrix obtained from your raw matrix or converted from your TAD-TAD probability matrix text file. This matrix can be used to get a replica population: copy it to a new directory, run the PGS-helper and choose option 3.
10. **Are the messages on screen while PGS is running saved somewhere?** Yes, the stdout log messages are accumulated in your working directory under `pyflow.data/logs/pyflow_log.txt`.
11. **What is the `pyflow.data/logs/pyflow_tasks_stdout_log.txt` for?** It contains detail information of all specific running jobs, i.e. processing matrix and modeling report (timing and scoring for all structures at all A/M cycles). For instance, you can search for “copy0.hms” in the log file and see how it performs from initial to final stages.
12. **Any reference for the PGS?**

  - Coming soon....

## alab

**class** `alab.contactmatrix` (*filename*, *genome=None*, *resolution=None*, *usechr=['#', 'X']*)

A flexible matrix instant that supports various methods for processing HiC contacts

### Parameters

- **filename** (*str*) – matrix file stored in hdf5 format or an integer for the matrix size to initialize an empty matrix instance
- **genome** (*str*) – genome e.g. 'hg19', 'mm9'
- **resolution** (*int*) – the resolution for the hic matrix e.g. 100000
- **usechr** (*list*) – containing the chromosomes used for generating the matrix

### matrix

*numpy 2d array* – storing all infor for the hic contact matrix

### idx

*numpy structure array* – matrix index

### genome

*str* – the genome

### resolution

*int* – resolution for the contact matrix

### applied (*method*)

**assignDomain** (*domain*, *pattern=''*)

Load Domain information

### Parameters

- **domain** (*alab.files.bedgraph instance*) – bedgraph for domain definition
- **pattern** (*str*) – a string use to filter the flags in the bedgraph

**buildindex** (*\*\*kwargs*)

**columnsum** ()

**fmaxScaling** (*fmax, force=False*)

use fmax to generate probability matrix for uniform fmax, simply divide the matrix by fmax and clip to 1 for neighbouring contact fmax  $P[i,j] = F[i,j]/\min(fmax[i], fmax[j])$

**fmaximization** (*\*\*kwargs*)

**getDomainMatrix** (*domainChrom, domainStartPos, domainEndPos, rowmask, minSize=1, maxSize=None*)

Return a submatrix defined by domainChrom, domainStartPos, domainEndPos

#### Parameters

- **domainChrom** (*str*) – domain chromosome e.g. 'chr1'
- **domainStartPos** (*int*) – start position e.g. 0
- **domainEndPos** (*int*) – end position e.g. 700000
- **minSize** (*int, > 0*) – min domain size
- **maxSize** (*int, optional*) – max domain size, in bins if the domain is larger than a given number of bins, this function will return None

**getICP** (*index*)

return inter-chromosomal proportion of a given bin index

**getfmax** (*method='UF', minSize=1, maxSize=2000, removeZero=False, boxplotTrim=False, off-diag=1, target='median'*)

calculate fmax based on different methods

#### Parameters

- **method** (*str*) – NM #neighbouring max UF #uniform fmax
- **target** (*str*) – 'mean'/'median'

**identifyInterOutliersCutoff** (*N=100*)

Identify interchromosome outliers' cutoff Do an N round random choice as the original contact freq distribution and estimate the sample std for every contact freq If the sample std is larger than half of the frequency (contact #), label this contact frequency as spurious cutoff is set to the number that first consecutive 2 non-spurious frequency from the right side (scan from high frequency to low)

**iterativeFmaxScaling** (*domainAverageContacts=23.2, tol=0.01*)

Automatic fmax scaling to get domain level matrix and match the rowsum average domain level matrix to domainAverageContacts

**krnorm** (*mask=None, force=False, \*\*kwargs*)

using krnorm balancing the matrix (overwriting the matrix!)

#### Parameters

- **mask** (*list/array*) – mask is a 1-D vector with the same length as the matrix where 1s specify the row/column to be ignored or a 1-D vector specifying the indexes of row/column to be ignored if no mask is given, row/column with rowsum==0 will be automatically detected and ignored
- **large\_mem** (*bool*) – when large\_mem is set to 1, matrix product is calculated using small chunks, but this will slowdown the process a little bit.

**makeDomainLevelMatrix** (*method='topmean', top=10, removeOutlier=True*)

Use domain INFO to generate Domain level matrix

**Parameters**

- **method** (*str*) – “topmean” or “median”
- **top** (*int*  $0 < top < 100$ ) – the top percentage to calculate the mean, top=10 means top 10% of the subdomain matrix
- **removeOutlier** (*bool*) – option to remove outlier using 1.5IQR

**makeIntraMatrix** (*chrom*)

subtract a chromosome matrix given a chromosome name

**Parameters** **chrom** (*str*, chromosome name e.g. 'chr1') –**plot** (*figurename*, *log=False*, *\*\*kwargs*)

plot the matrix heat map

**Parameters**

- **figurename** (*str*) –
- **log** (*bool*) – if True, plot the log scale of the matrix if False, plot the original matrix
- **clip\_max** (*float*) –
- **clip\_min** (*float*) – 2 options that will clip the matrix to certain value
- **cmap** (*matplotlib.cm instance*) – color map of the matrix
- **label** (*str*) – label of the figure

**plotSum** (*figurename*, *outlier=False*, *line=None*, *\*\*kwargs*)

Print the rowsum frequency histogram

**Parameters**

- **figurename** (*string*) – Name of the plot
- **outlier** (*bool*) – option to select plotting the outlier line, only functioning if ‘line’ parameter is set to None
- **line** (*float/array/list*) – draw vertical lines at a list of positions

**plotZeroCount** (*figurename*, *\*\*kwargs*)**range** (*chrom*)

return the index range for a give chromosome

**removeDiagonal** (*force=False*)**removePoorRegions** (*cutoff=1*, *usepvalue=0.1*, *force=False*)

Removes “cutoff” percent of bins with least counts

**Parameters**

- **cutoff** (*int*,  $0 < cutoff < 100$ ) – Percent of lowest-counts bins to be removed
- **usepvalue** (*float*,  $0 < usepvalue < 1$ ) – use this pvalue as correlation cutoff to remove bins whose pvalue greater than this cutoff will be removed

**rowsum** ()**save** (*filename*)

Save the matrix along with information in hdf5 file

**scale** (*cellaverage=1*)

Scale matrix so that average of cells is the given value. By default, the rowsum will be the number of rows/columns

**smoothGenomeWideHighValue** (*w=3, s=3, p=3, z=5, force=False*)

Use power law smoothing function to smooth high spikes in chromosomes blocks

**Parameters**

- **w** (*int*) – the window size, the smoothing is computed using target +/- w
- **s** (*int*) – weight of the location deviation
- **p** (*int*) – power of the location deviation
- **z** (*int*) – range of standard deviation to set cutoff

**smoothInterContactByCutoff** (*cutoff, w=3, s=3, p=3, force=False*)

given the cutoff, run a power law smoothing for the interchromosome matrix for contacts > cutoff

**vcnorm** (*iterations=1, mask=None, force=False*)

**class** `alab.tadmodel` (*probfile, nucleusRadius=5000.0, chromosomeOccupancy=0.2, contactRange=1, level=None*)

A wrapper to do IMP modeling in TAD level beads

**Parameters**

- **probfile** (*alab.matrix.contactmatrix instant*) – probability matrix at TAD level, `alab.matrix.contactmatrix` hdf5 format is required
- **nucleusRadius** (*float*) – radius of nucleus, default 5000(nm)
- **contactRange** (*int*) – folds for surface-surface contact coefficient
- **level** (*loglevel,* ) – default:None will record everything during caculation debug, info, warning, error, critical are supported

**CondenseChromosome** (*rrange=0.5*)

Collapse chains around centromere beads

**Parameters** **rrange** (*float*) – scale parameter in [0,1] for the radius limit

**SimulatedAnnealing** (*hot, cold, nc=10, nstep=500*)

perform a cycle of simulated annealing from hot to cold

**SimulatedAnnealing\_Scored** (*hot, cold, nc=10, nstep=500, lowscore=10*)

perform a cycle of simulated annealing but stop if reach low score

**cache\_coordinates** ()

**cgstep** (*step, silent=False*)

perform conjugate gradient on model using scoring function sf

**evaluateRestrains** (*restraintset, tolerance=0.05*)

**mdstep** (*t, step, gamma=0.1, silent=False*)

**mdstep\_withChromosomeTerritory** (*t, step*)

perform an mdstep with chromosome territory restraint

**Parameters**

- **t** (*int*) – temperature
- **step** (*int*) – optimization steps

**saveCoordinates** (*filename, prefix*)

**savepym** (*filename*)

**savepym\_withChromosome** (*filename, s=1, v=1*)

```

set_consecutiveBeads (lowprob=0.1)
set_contactRestrains (actdist, kspring=1)
set_coordinates (coordinates=None)
set_excludedVolume (ksping=1, slack=10)
set_fmaxRestrains (kspring=1)
set_nucleusEnvelope (kspring)
shrinkingOptimization (drange, shrinkScore, minscore, interScale)
updateScoringFunction (restraintset=None)

```

**class** `alab.modelstructures` (*filename, usegrp*)

Instance manipulating hdf5 packed model structures take .hms file generated by tad modeling

#### Parameters

- **filename** (*str*) – model result file \*.hms
- **usegrp** (*str*) – group label array, usually assigned with probability prefix like ['1', '0.2']

**class** `alab.structuresummary` (*target, usegrp=None, nstruct=10000, pid=10, \*\*kwargs*)

This class offers a series of methods to study the model structure populations.

#### Parameters

- **target** (*str*) – the output directory for population structures, containing copy\*.hms files or can be seen as summary file \*.hss
- **usegrp** (*str*) – the probability key used in modeling, e.g. p005j
- **nstruct** (*int*) – number of structures to read

**findBinIndex** (*chrom, start, end*)

To find bead indexes given a chromosome region

#### Parameters

- **chrom** (*str*) – chromosome, should match the .idx representation
- **start, end** (*int*) – location range

#### Returns

**Return type** Bin indexes array, or None if there is no valid ones

**getABCopyMeanBeadRadialPosition** (*nucleusRadius=5000.0*)

Calculate mean radial position for every bead in structures, and differentiate diploid copy into A/B by inner or outer radial position

**Parameters** **nucleusRadius** (*float*) – radius of nucleus, default 5000(nm)

**Returns** Two 1-D array

**Return type** mean radian position for all beads, and first array contains the inner bead in the diploid genome.

**getAveragePairwiseDistance** (*form='list'*)

Calculate pairwise distance mean for each pair of beads in the structure population

**Parameters** **form** (*str*) – the return form of the function 'list' return the list form 'matrix' return the matrix form

**getBeadRadialPosition** (*beads*, *nucleusRadius=5000.0*)

Calculate radial position for every bead in the input list *beads*

**Parameters**

- **beads** (*array-like*) – list of all beads to calculate
- **nucleusRadius** (*float*) – radius of nucleus, default 5000(nm)

**Returns** **M\*N matrix** – M = len(*beads*) N = number of structures in population

**Return type** radial position for all beads in the input and all structures in population

**getChromosomeRadialPosition** (*chrom*, *nucleusRadius=5000.0*)

Calculate radial position for the *chrom*

**Parameters**

- **chrom** (*str*) – the chromosome to calculate
- **nucleusRadius** (*float*) – radius of nucleus, default 5000(nm)

**Returns** **2N\*1 vector**

**Return type** radial position for the chromosome in all structures in population

**getContactMap** (*contactRange=1*)

Return contact matrix format contact heatmap

**getPairDistance** (*bead1*, *bead2*)

Calculate pairwise distance across all structures

**Parameters** **bead1**, **bead2** (*int*) – two bead in a pair, input to calculate distance

**Returns**

**Return type** numpy array that has distance for the bead pair.

**plotRadialPosition** (*figurename*, *chrom*, *format='pdf'*, *color='dodgerblue'*, *nucleusRadius=5000.0*)

Plot Radial Position of beads for given chromosome

**Parameters**

- **figurename** (*str*) – name of the figure
- **chrom** (*str*) – given chromosome name
- **color** (*str*) – given the color for plotting

**save** (*filename*)

save all info into disk

**totalRestrains**

returns: **numpy array** :rtype: all restrains for each structure

**totalViolations**

returns: **numpy array** :rtype: all violations for each structure

**violationPercentage**

returns: **numpy array** :rtype: violation percentage for each structure

## alab.files

**class** `alab.files.modelgroup` (*grouphandler*, *genome*, *idx*)

### Organization of the .hmat file

PGS saves a probability matrix in a binary hdf5 file with extension hmat. In the following we describe the file format. The file can be operated using alab api (see [Alberlab API Reference](#))

- matrix (n \* n numpy 2D matrix storing the hic contacts)
- idx (n \* 4 numpy struct array consist of [chrom, start, end, flag] fields)
- genome (cPickle serialized string)
- resolution (cPickle serialized string)
- appliedMethods (cPickle serialized string, storing all process done after creating the matrix)

### Organization of the .hms file

The output of each modeling step is dumped in a file with .hms extension. One .hms file contains information of a structure that evolve from the highest to lowest probability levels in theta list. Usually, only the final model extracted from this file is used for further analysis. In the following we describe the file format. The file can be operated using alab api (see [Alberlab API Reference](#))

- genome (cPickle serialized string)
- resolution (cPickle serialized string)
- idx (n \* 4 numpy struct array consist of [chrom, start, end, flag] fields)
- <group name 1>
- <group name 2>
- ...

Group names are usually threshold values, each group consists the following components:

- xyz (n \* 3 array, coordinates)
- r (n \* 1 array, radii)
- log (cPickle serialized string, all processing logs)
- pym (serialized pym file content)

## Organization of the .hss file

A structure summary file, .hss can be generated once all final structures are successfully generated. In the following we describe the file format. The file can be operated using alab api (see [Alberlab API Reference](#))

- genome (cPickle serialized string)
- resolution (cPickle serialized string)
- idx (n \* 4 numpy struct array consist of [chrom, start, end, flag] fields)
- usegrp (cPickle serialized string of threshold)
- nbead (cPickle serialized int, number of representative beads in haploid)
- nstruct (cPickle serialized int, number of total structures)
- radius (n \* 1 array of bead radii)
- coordinates (nstruct \* n \* 3 array, coordinates for all structures)
- score (1 \* nstruct array of optimization score)
- consecutiveViolations
- contactViolations
- intraRestrains
- interRestrains

## Activation distance file

We start the modeling from random configurations for each structure and assign contacts between TADs that occur in 100% of the population (see [Methods](#)). Since we increase the number of restraints gradually, we need to assign contacts to a set of structures in the population at every A/M cycles. To do so, we compute the cumulative histogram and determine the distance cutoff according to the probability of a TAD pair in contact. The files are saved under result/actDist (the first 4 columns are TAD1, TAD2, contact probability, distance\_cutoff\_to\_activate\_contact).
